

Built-in Functions

Function Call

The general form of a function call:

```
function_name(arguments)
```

The rules for executing a function call:

1. Evaluate the arguments.
2. Call the function, passing in the argument values.

Terminology:

- *Argument*: a value given to a function
- *Pass*: to provide to a function
- *Call*: ask Python to evaluate a function
- *Return*: pass back a value

Example function calls:

```
>>> abs(-23)
23
>>> abs(56.24)
56.24
```

Function `dir`

Python has a set of built-in functions. To see the list of built-in functions,

run `dir(__builtins__)`:

```
>>> dir(__builtins__)< br/> ['ArithmeticError', 'AssertionError',
'AttributeError', 'BaseException', 'BufferError', 'BytesWarning',
'DeprecationWarning', 'EOFError', 'Ellipsis', 'EnvironmentError',
'Exception', 'False', 'FloatingPointError', 'FutureWarning', 'GeneratorExit',
'IOError', 'ImportError', 'ImportWarning', 'IndentationError', 'IndexError',
'KeyError', 'KeyboardInterrupt', 'LookupError', 'MemoryError', 'NameError',
'None', 'NotImplemented', 'NotImplementedError', 'OSError', 'OverflowError',
'PendingDeprecationWarning', 'ReferenceError', 'ResourceWarning',
'RuntimeError', 'RuntimeWarning', 'StopIteration', 'SyntaxError',
'SyntaxWarning', 'SystemError', 'SystemExit', 'TabError', 'True',
'TypeError', 'UnboundLocalError', 'UnicodeDecodeError', 'UnicodeEncodeError',
'UnicodeError', 'UnicodeTranslateError', 'UnicodeWarning', 'UserWarning',
'ValueError', 'Warning', 'ZeroDivisionError', '_', '__build_class__',
'__debug__', '__doc__', '__import__', '__name__', '__package__', 'abs',
'all', 'any', 'ascii', 'bin', 'bool', 'bytearray', 'bytes', 'callable',
```

```
'chr', 'classmethod', 'compile', 'complex', 'copyright', 'credits',  
'delattr', 'dict', 'dir', 'divmod', 'enumerate', 'eval', 'exec', 'exit',  
'filter', 'float', 'format', 'frozenset', 'getattr', 'globals', 'hasattr',  
'hash', 'help', 'hex', 'id', 'input', 'int', 'isinstance', 'issubclass',  
'iter', 'len', 'license', 'list', 'locals', 'map', 'max', 'memoryview',  
'min', 'next', 'object', 'oct', 'open', 'ord', 'pow', 'print', 'property',  
'quit', 'range', 'repr', 'reversed', 'round', 'set', 'setattr', 'slice',  
'sorted', 'staticmethod', 'str', 'sum', 'super', 'tuple', 'type', 'vars',  
'zip']
```

Function `help`

To get information about a particular function, call `help` and pass the function as the argument. For example:

```
>>> help(abs)  
Help on built-in function abs in module builtins:  
abs(...)  
    abs(number) -> number  
  
    Return the absolute value of the argument.
```

Optional arguments

In the description of function `pow` below, the square brackets around `[, z]` indicate that the third argument is optional:

```
>>> help(pow)  
Help on built-in function pow in module builtins:  
  
pow(...)  
    pow(x, y[, z]) -> number  
  
    With two arguments, equivalent to x**y. With three arguments,  
    equivalent to (x**y) % z, but may be more efficient (e.g. for longs).
```

Function `pow` can be called with either two or three arguments:

```
>>> pow(2, 5)  
32  
>>> pow(2, 5, 3)  
2
```
